

aLIGO One Arm Test Commissioning Update: So far, so good.

Kawabe + many people

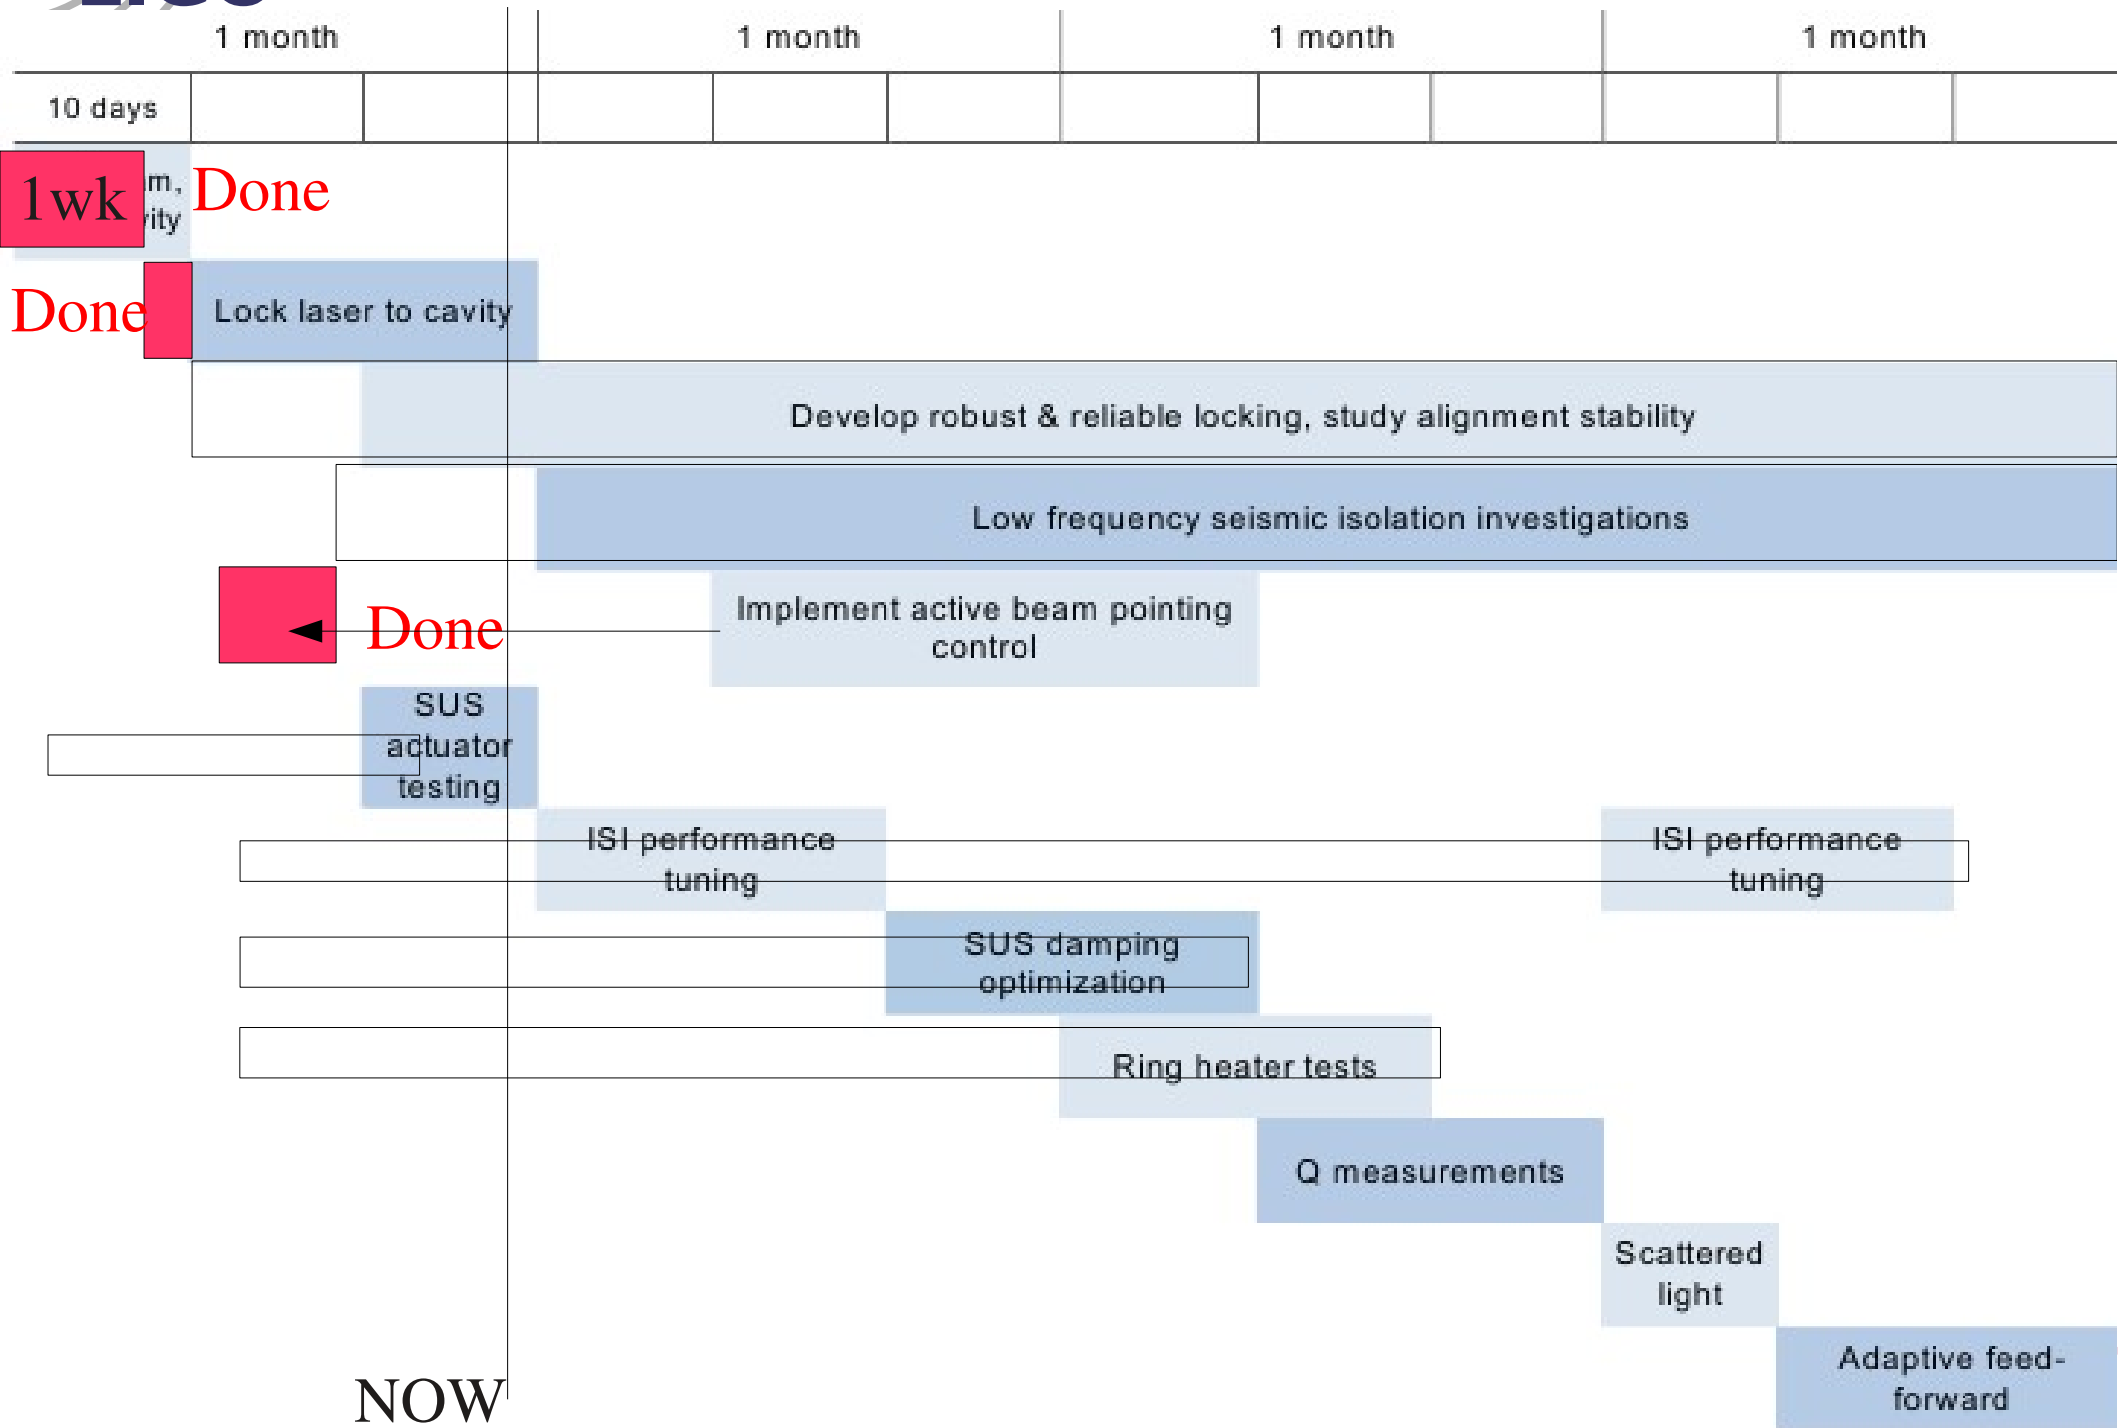

Initially Proposed Straw Man (T1100080)

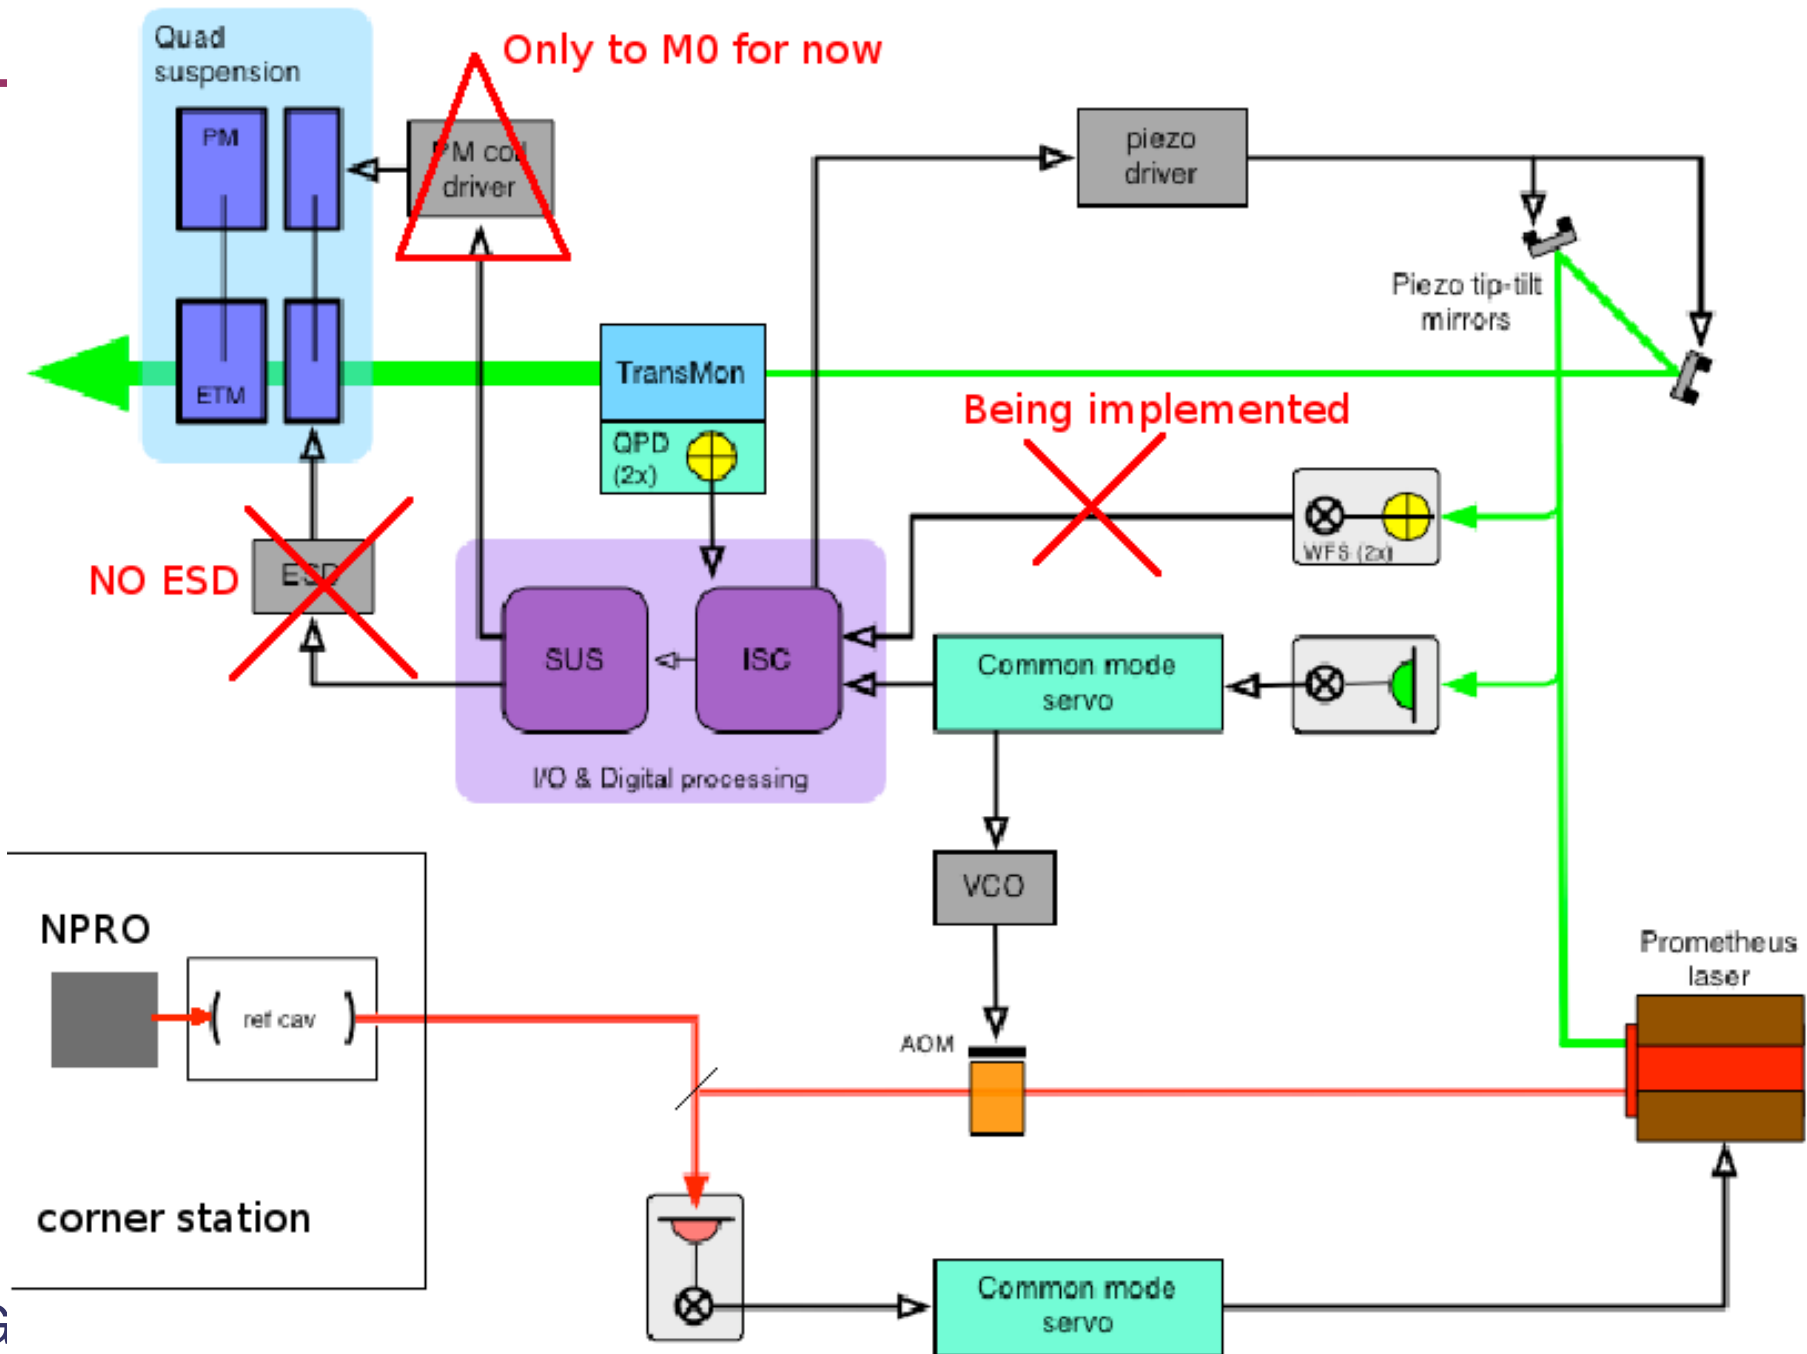

Reality

- 2 days to shoot the beam down through the tube
- 5 additional days until the first lock
- Both baffle diodes and ccds are essential for alignment.
- Working PDH diode and demod are essential for alignment.
 - Use it instead of looking at the video for flashing, as you can't see it “flashing” until the laser is half-locked to the cavity.
- Working PLL is essential for alignment.
 - Free running freq. noise is large enough to make the PDH error blurry.

ISC: Almost everything works

- PLL UGF: 22kHz (about the same as design)
- PDH UGF: about 12kHz (as opposed to 2kHz design)
- Cavity lock lasts for hours
- VCO offloading to ETM path for “slowing” cavity (M0-only and BW very small for now)
- Calibrated spectrum (more on this later, G1200752)
 - Very good length calibration using VCO
 - Noise dominated by TM vibration $f < 1.2$ Hz or so (as opposed to $f < 0.5$ Hz initial estimate)

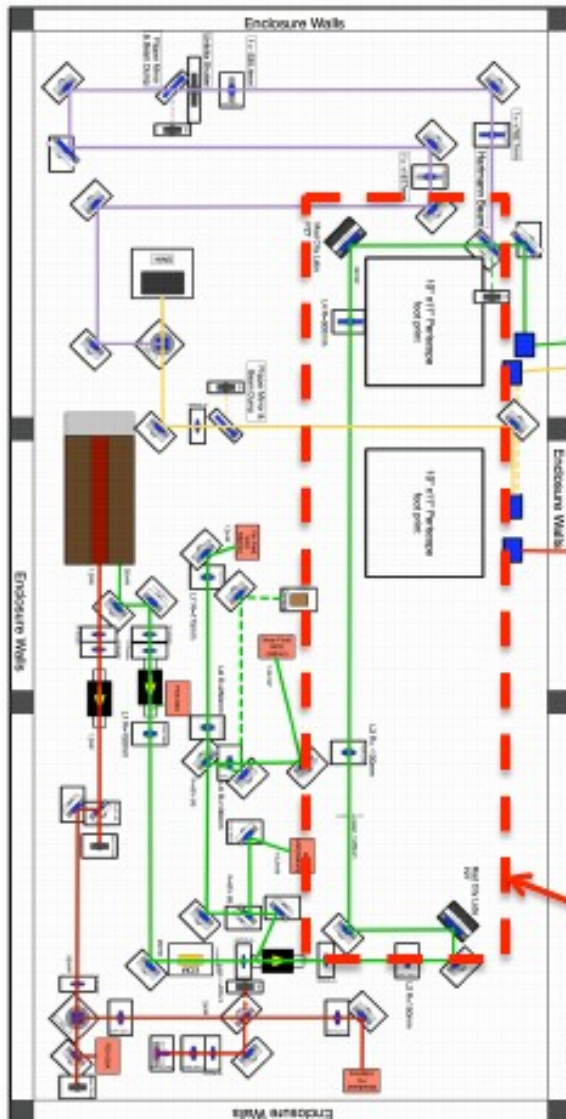

- PDH performance (BW~12kHz) better than design
- Gives more headroom for ALS comm and diff feedback

Quad Feedback

- ETMY Longitudinal-to-Pitch coupling mitigation.
- Longitudinal feedback (at the TOP) couples into small Pitch signal (inherent in the mechanical suspension).
- Filter design to reduce this coupling
 - Model shows 76 pole-zero pairs, this is too hard to implement.
 - Reducing pairs which cancel, less than 10% different and above ~ 3.5 Hz.
- Work in progress.

- Active pointing control was implemented
 - Open loop pointing error meets the spec (Stochino)
- Fringe visibility of REFL 50-60%
- WFS as a sensor is being implemented
 - Gouy telescope redone (initial design produced tiny beam)
 - Possibility of control later
- Slow control (Beckhoff, OPC)
 - Most of the things work
 - No automation yet (auto locker for PLL and PDH)
 - OPC-EPICS translation issues being investigated

ALS Table

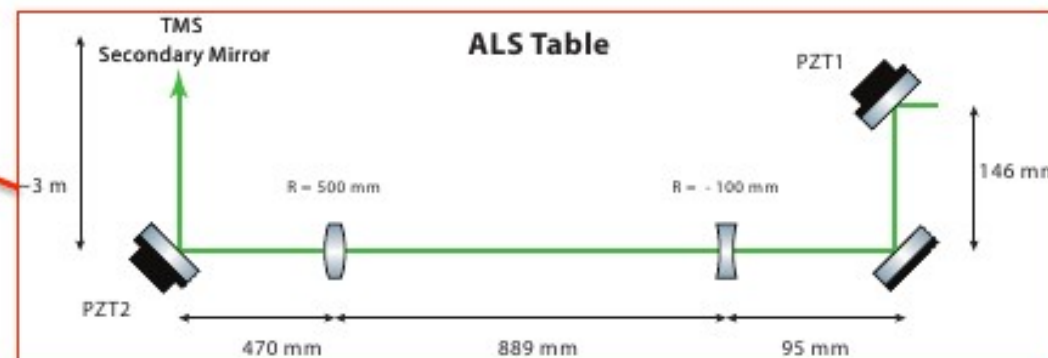

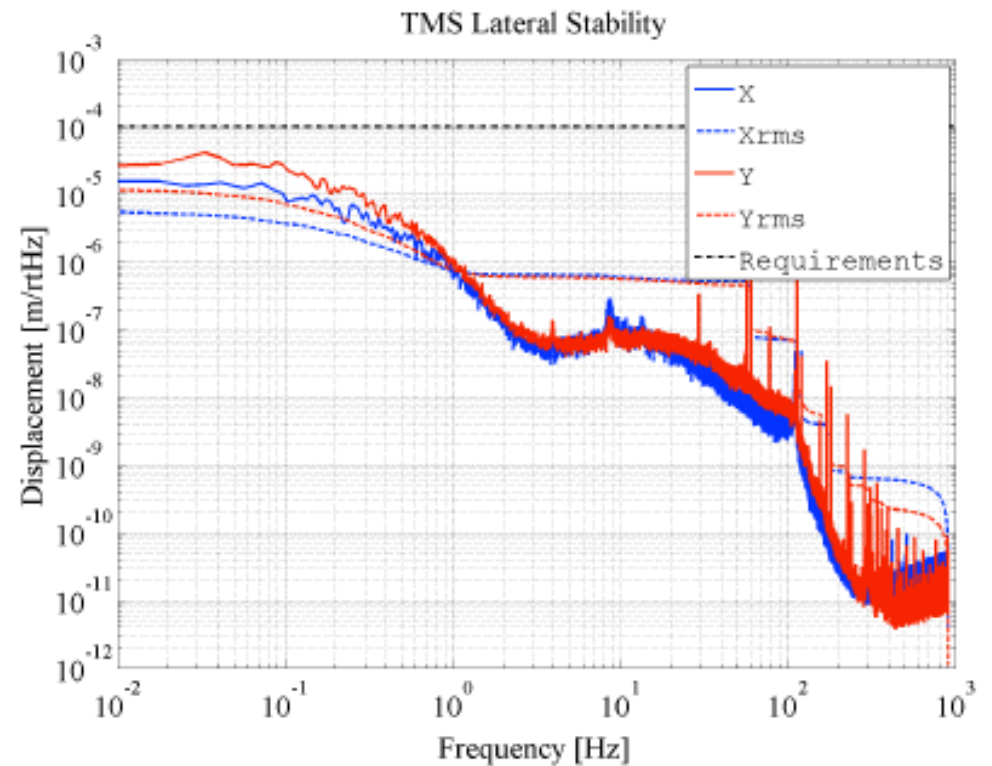

TMS Table

- QPD-PZT loops closed (UGF ~ 10 Hz)
- Measured PZT displacement
- Derived table-beam relative displacements through ALS table ABCD matrix

QPDS

Note: data is the equivalent OPEN LOOP ERROR, and the requirement is for CLOSED LOOP. UGF=10Hz, so it looks like both angle and displacement already meets the requirements.

- Damping characterization/optimization effort.
 - Plot by Kissel
 - Spec-wise, long way to go: IY-EY < 10nm rms for $f < 0.5\text{Hz}$ with slow signal from PDH offloaded to EY
- Length-PIT actuation decoupling effort.
- Sensing diagonalization effort.

- Some trouble in ISI isolation.
 - Need a better high freq. (e.g. 1 Hz) performance
- See Vincent/Fabrice's presentation.
- Despite these, we're already close to low frequency spec (IY-EY < 250 nm rms w/o global feedback).

-
- See Aidan's presentation.
